Task on CloudFront & Route 53

Objective of the Task

The objective of this task is to **design and develop a premium-quality, fully responsive static web page (index.html)** that showcases the professional profile of **Arjumand**, an AWS & DevOps expert.
The page must provide a highly engaging visual experience using **advanced animations, modern UI elements, graphical effects, and interactive components**, while also presenting detailed information about AWS and DevOps tools and offered services.

This task aims to:

1. **Create a visually striking and animated landing page** using modern gradients, blob backgrounds, neon glow effects, and smooth transitions.
2. **Showcase 20+ AWS and DevOps tools** in a graphical and organized manner for professional branding.
3. **Provide interactive service sections or modals** for describing DevOps services clearly and attractively.
4. **Implement a responsive navigation bar** with smooth scrolling and hover animations for enhanced UX.
5. **Ensure full mobile, tablet, and desktop responsiveness**, delivering a premium, polished user experience.
6. **Highlight Arjumand's skills, expertise, and DevOps services** through a high-end UI that resembles a $500+ professional portfolio website.

If you want, I can also write:
✅ A full detailed **scope**
✅ **Deliverables**
✅ **User flow**
✅ Or the **complete index.html** file with all animations and graphics.

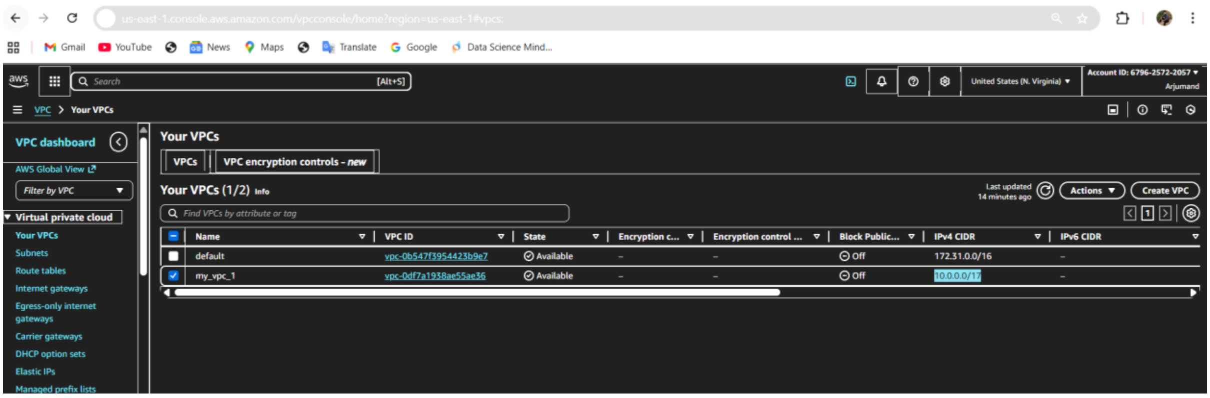
1. Configure VPC peering in cross regions.

Step-by-step

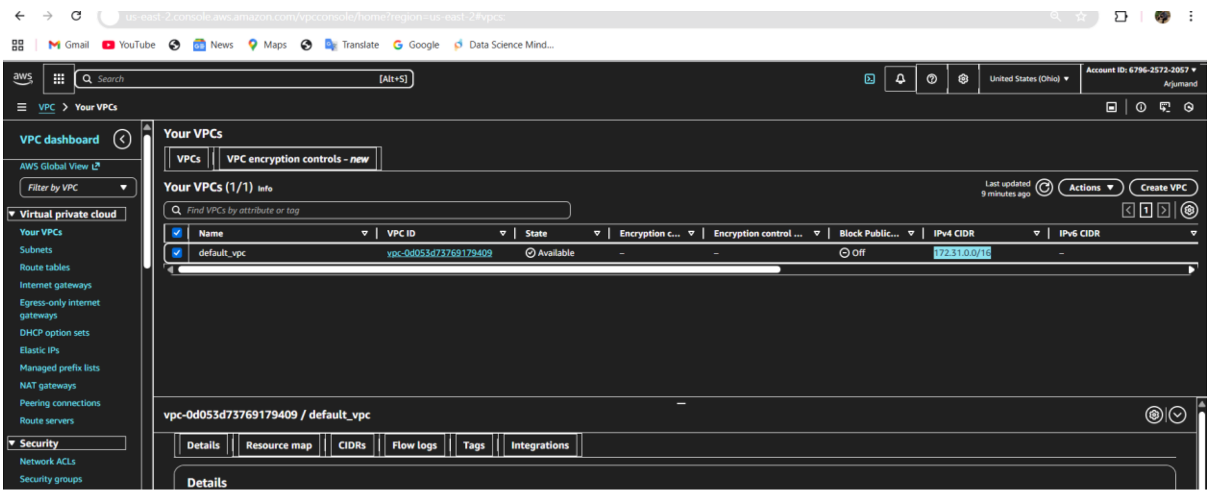
- **Create VPC A** in Region 1 (e.g., us-east-1) and VPC B in Region 2 (e.g., ap-south-1).
- Go to **VPC** → **Peering Connections** → **Create Peering Connection**.
    - Requester VPC: VPC A
    - Accepter VPC: VPC B
    - Select "**Another Region**" option.
- Go to the **Accepter region**, open the peering request → **Accept**.

- Update **route tables**:
    - In VPC A route table → add route to VPC B CIDR through the peering ID.
    - In VPC B route table → add route to VPC A CIDR through the peering ID.
- Update **security groups** to allow traffic between VPCs.

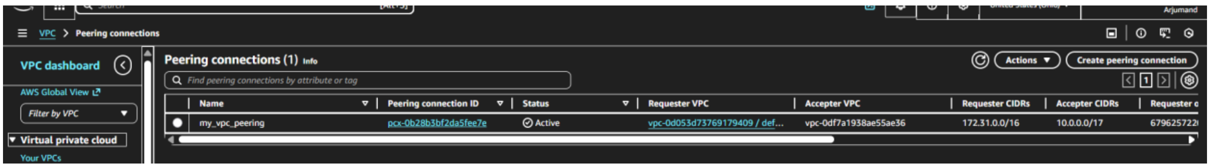
- Created vpc1 in N.verginia region and created rout and subnet and created internet and attached to internet.



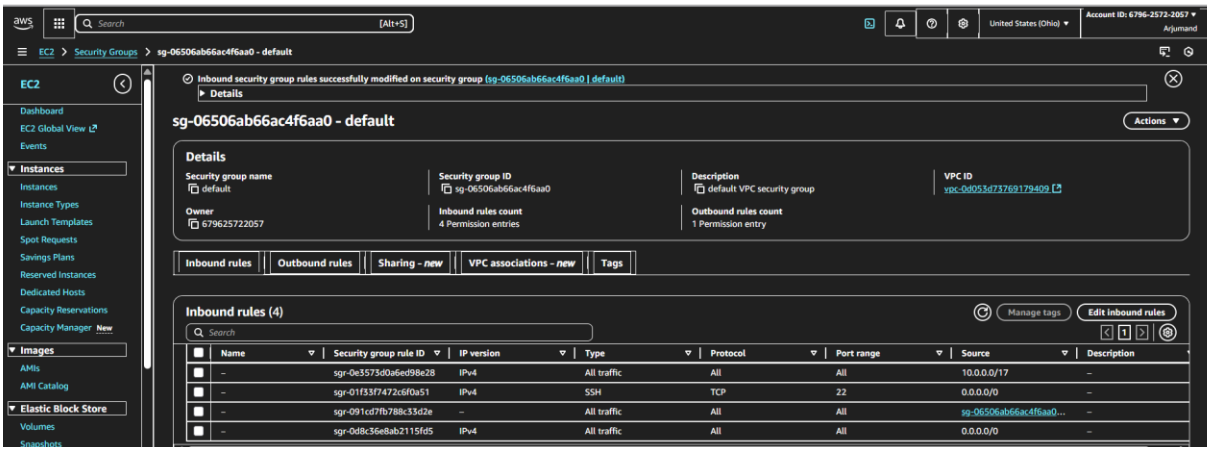
- Created vpc 2 in ohio region and created subnet, route table, internet gateway.

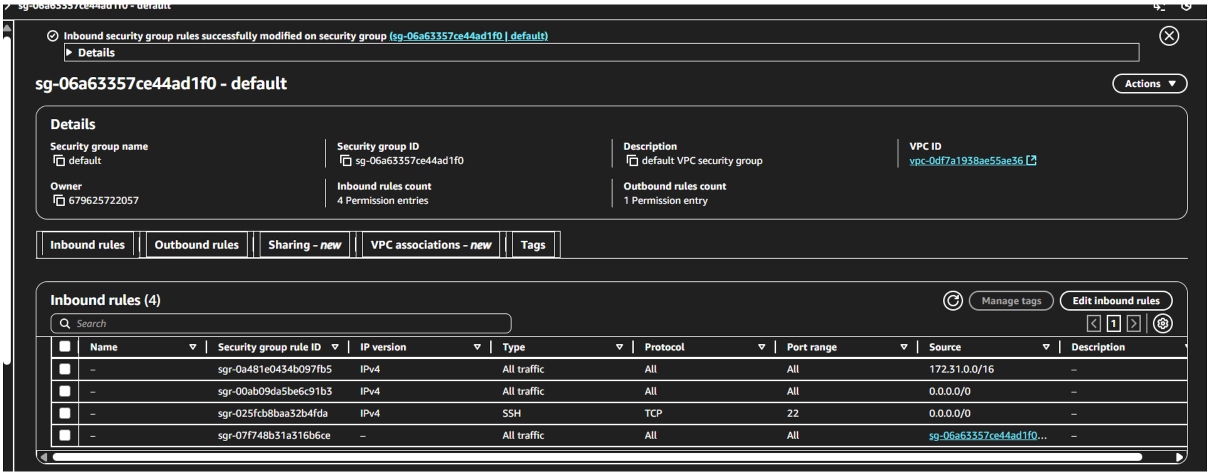


VPC peering is created between 2 regions of vpc

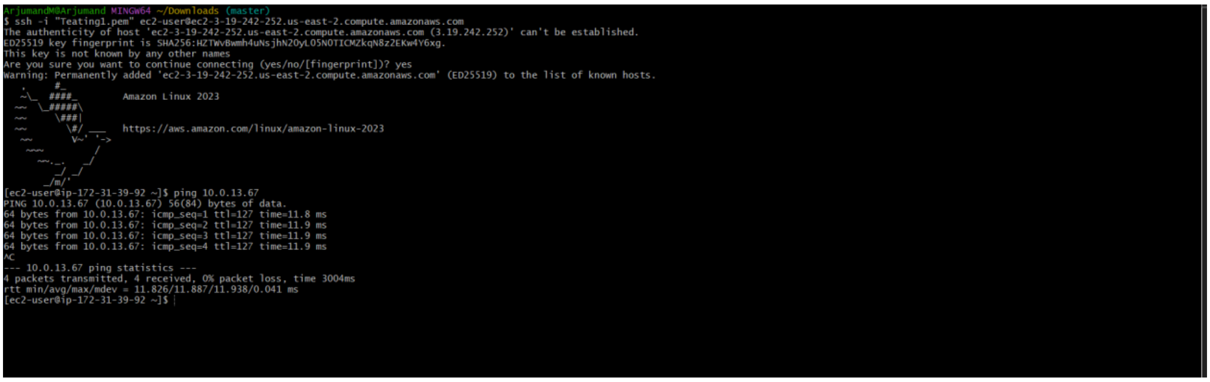


Added cross cidr vpc number in each route table

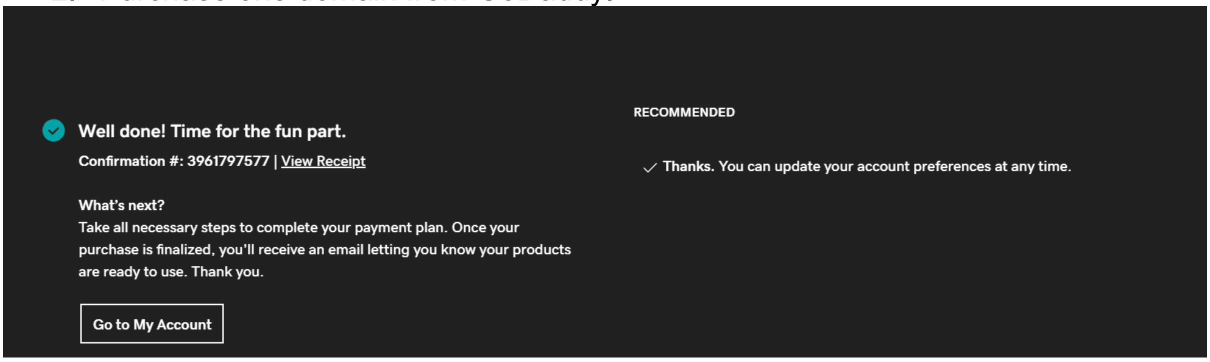


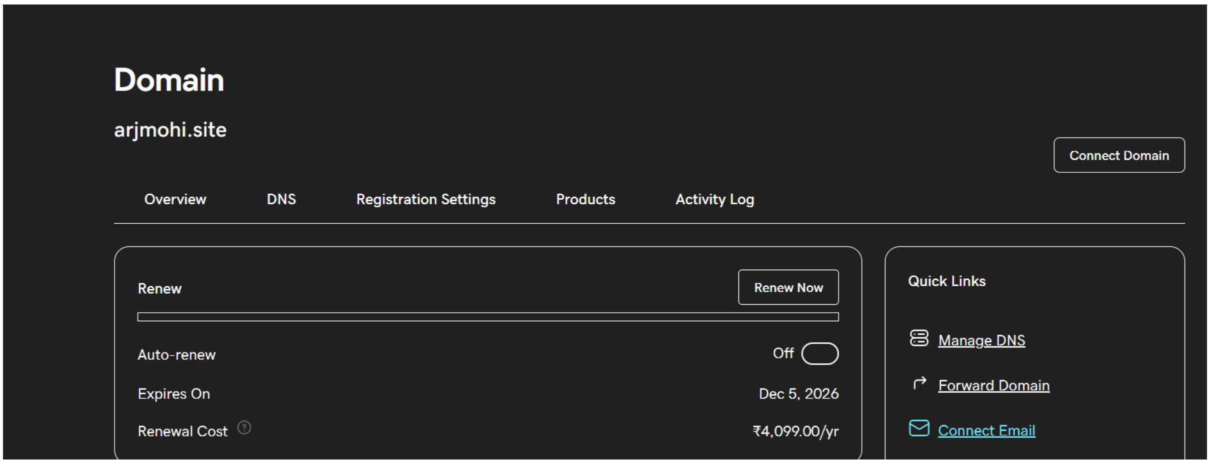


We have successfully pinged one ec2 to second vpc using peering connection.



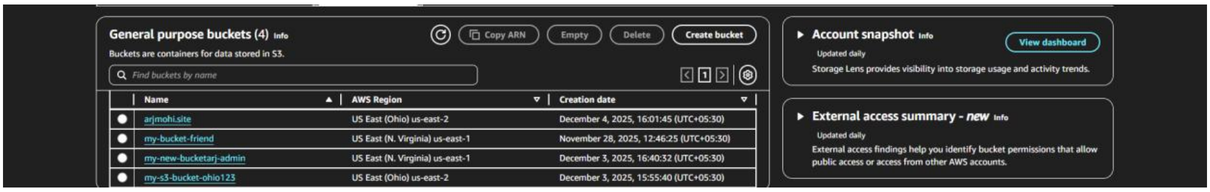
2. Purchase one domain from GoDaddy.

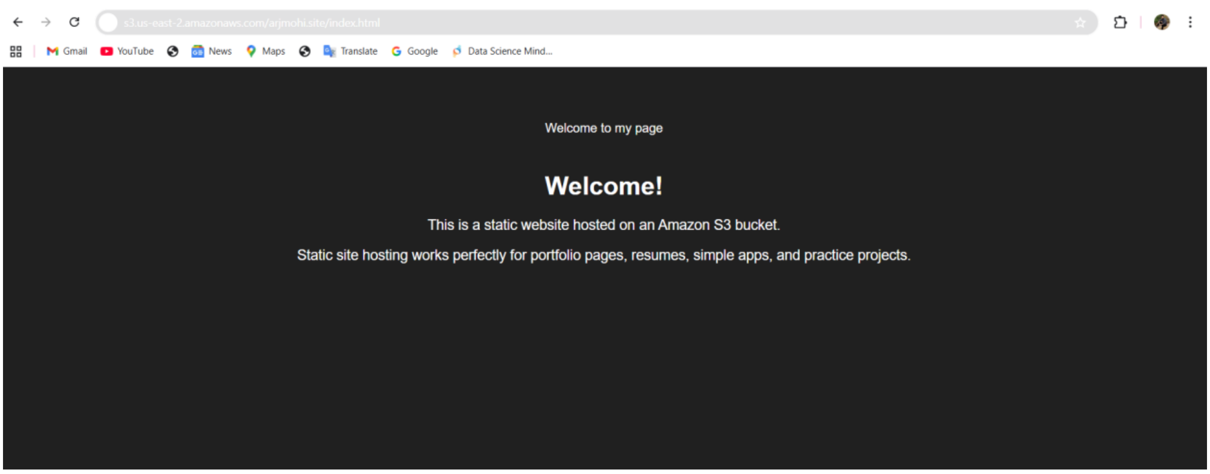




3. deploy static website in S3.

- I have created s3 bucket with my domain name and then uploaded index and error file, gave public permission.
- Deployed static page on web.





4. Create a CDN and attach one SSL certificate.

5. Create a Route 53 hosted zone and map the domain with the CDN.

- First, I created a **CloudFront CDN distribution** to deliver my website content globally with low latency.
- I configured the CDN's **origin** to point to my S3 static website endpoint.
- Next, I requested an **SSL/TLS certificate in AWS Certificate Manager (ACM)** for my domain.
- The certificate included both **arjmohi.site** and www.arjmohi.site.
- After validation, I attached this SSL certificate to the **CloudFront distribution**.
- This ensures all HTTPS traffic to the domain is secure and encrypted.
- Then, I created a **Hosted Zone** for the domain in **Route 53**.
- Inside the hosted zone, I added **A records (Alias)** pointing to the CloudFront distribution.
- I updated the domain’s nameservers in GoDaddy to match the Route 53 nameservers.
- After propagation, the domain successfully mapped to the CDN and served securely over HTTPS.

Let me know if you want this in **paragraph format**, **bullet points**, or **more technical**!

Bucket Versioning
Edit
Versioning is a means of keeping multiple variants of an object in the same bucket. You can use versioning to preserve, retrieve, and restore every version of every object stored in your Amazon S3 bucket. With versioning, you can easily recover from both unintended user actions and application failures. Learn more
Bucket Versioning
Disabled
Multi-factor authentication (MFA) delete
An additional layer of security that requires multi-factor authentication for changing Bucket Versioning settings and permanently deleting object versions. To modify MFA delete settings, use the AWS CLI, AWS SDK, or the Amazon S3 REST API. Learn more
Disabled
Bucket ABAC
Edit
Attribute-based access control (ABAC) is an authorization strategy that defines permissions based on attributes. With ABAC, you can attach tags to your general purpose buckets and AWS Identity and Access Management (IAM) entities (users or roles), then scale access to objects in your S3 general purpose buckets using tag-based policies. Learn more
ABAC status

AWS COMPUTE
Amazon EC2
Elastic virtual machines for scalable, high-availability applications.
How I use this in real projects
• Designing autoscaling groups behind Application Load Balancers for stateless web tiers.
• Creating hardened AMIs with cloud-init and configuration management.
• Blue/green and rolling deployments integrated with CodeDeploy/CodePipeline.
Key capabilities
• Horizontal and vertical scaling with multiple instance families.
• Integration with EBS, EFS, ALB/NLB, VPC security groups and IAM roles.
• Spot instances and Savings Plans for cost optimisation.
Autoscaling
ALB / NLB
Bastion-less access via SSM
